Interface Research A

A brain-computer interface (BCI) recognizes the intent of the user through brain signals, decodes neural activity, and translates it into output commands that accomplish the user's goal. BCI technology has the potential to restore lost or impaired functions of people severely disabled by various devastating neuromuscular disorders or spinal cord damage, and to enhance or augment functions in healthy individuals.

An EEG-based brain-computer interface is the most preferred type of BCI for studying. EEG signals are processed and decoded in control signals, which a computer or a robotic device perceives readily. The processing and decoding operation is one of the most complicated phases of building a good-quality BCI.

Brain-computer interface - Wikipedia

Brain Computer Interface (BCI) forges a direct, online communication between brain and machine, independent from the user's physical abilities and represents a new way to augment human capabilities. They translate the user's intentions into outputs or actions by means of machine learning techniques.
